**ABSTRACT:** The infrared (IR) spectra of sulfanilamide **1** and of its azanion (counter ion Na<sup>+</sup>) **2** have been measured in dimethyl sulfoxide (DMSO) solutions. The density functional theory (DFT) B3LYP 6-31++G(*d,p*) computations performed adequately describe the experimental spectroscopic data, including the corresponding frequency isotopic shifts. In agreement between theory and experiment, the conversion of sulfanilamide **1** into azanion **2** results in strong frequency decreases of the asymmetrical and symmetrical vibrations of the SO<sub>2</sub> group: predicted 122 cm<sup>-1</sup>, measured 140 cm<sup>-1</sup> in solution (total values), as well as in other essential IR spectral changes. According to the computations, the strongest changes in the steric structure take place at and next to the azanionic center. The new (azanionic) charge is distributed, as follows: 0.08e<sup>-</sup>, 0.23e<sup>-</sup>, and 0.12e<sup>-</sup> are delocalized over the amino, phenylene, and sulfonic groups, respectively, and 0.57e<sup>-</sup> of it remain localized at the azanionic center. © 2006 Wiley Periodicals, Inc. *Int J Quantum Chem* 107: 1752–1764, 2007

## Introduction

Gelmo [1] was the first to prepare sulfanilamide (formula 1) almost 100 years ago. This compound was the simplest representative of a large series of sulfonamide medicines. Their strong antibacterial activity combined with low toxicity was discovered by Domagk in 1934 (Nobel Prize 1939) [2]. Under trade names such as Prontosil album, and Streptocide album, sulfanilamide is used against various bacterial infections in human and veterinary medical practices [3, 4].

The early work on infrared (IR) spectra of sulfanilamide was reviewed by Bellamy [5], together with the main band assignments. A detailed empirical assignment of IR and Raman bands of sulfanilamide was reported 40 years ago [6]. The complete IR band assignment of the sulfanilamide molecule was recently performed using ab initio Hartree–Fock (HF) 3-21G force-field calculations [7]:

**1**

**2**

In contrast, the conversions of neutral molecules into radical anions, carbanions, azanions, etc., are accompanied with essential changes in the vibration spectra. So these changes are very informative for the structural variations that result from the above conversions [8, 9]. The molecule  $\rightarrow$  anion conversions for many species have recently been studied successfully by ab initio and/or density functional theory (DFT) and IR spectra (Refs. [10–14] and references therein). The title compound is an interesting and convenient object of such investigations, as it contains several characteristic groups (e.g.,  $\text{SO}_2$ ,  $\text{NH}_2$ ) and can easily be converted into a stable azanion. Neither the IR spectra nor structure

of sulfanilamide azanion (formula 2) have been studied theoretically or experimentally.

The purpose of the present investigation is to follow the spectral and structural changes, caused by the conversion of sulfanilamide molecule 1 into the corresponding azanion 2 on the basis of both DFT B3LYP 6-31(*d,p*) computations and spectroscopic experiments.

## Computations

DFT computations (full optimization) of the title species were performed using the Gaussian 98 program package [15]. This theory was the groundwork of series of cost-effective methods to approximate electron correlation effects [16]. We employed the B3LYP functional, which combines Becke's three-parameter nonlocal exchange with the correlation functional of Lee, Yang, and Parr [17, 18], adopting a 6-31++G(*d,p*) basis set without any symmetry restriction. For every structure, the stationary points found on the molecular potential energy hypersurfaces (PEHS) were characterized using standard analytical harmonic vibrational analysis. The absence of negative frequencies or negative eigenvalues of the second-derivative matrix confirmed that the stationary points correspond to global minima on the PEHS [16]. The use of 6-31++G(*d,p*) basis set in DFT computations has recently resulted in better or equally good spectral and structural predictions, compared with other basis sets for both organic molecules and anions [11, 12, 19, 20]. No scaling in the density functional force field was done. A standard least-squares program was used to calculate the single-parameter linear regression indices.

## Experimental

We prepared sulfanilamide- $\text{d}_0$  by the classical Gelmo method [1] from acetanilide (Scheme 1). After recrystallization, we obtained white needles of 1, m.p. 165–166°C (literature m.p. 164.5–166.5°C) [3].

To prepare sulfanilamide- $^{15}\text{N}$  (in the sulfonamido group), we used  $^{15}\text{NH}_3$  (Isocommezz, 97.3% at. enrichment) for the second reaction of Scheme 1. We prepared sulfanilamide- $\text{d}_4$  (in amino groups) by threefold, dissolving 1 in  $\text{D}_2\text{O}$  (Fluka, 99.8% at. enrichment) and evaporation of the solvent in vacuo. The sulfanilamide azanion 2 (counter ion  $\text{Na}^+$ ) and its isotope-labeled derivatives were pre-

**SCHEME 1.** Preparation of sulfanilamide **1** by Gelmo's method.

pared by adding dimethyl sulfoxide (DMSO)- $d_6$  solutions of sulfanilamide- $d_0$ , - $d_4$ , and - $^{15}\text{N}$  to excess of  $\text{NaOCH}_3$ - $d_0$  and - $d_3$ , and filtration of the reaction mixture by a syringe filter. The conversion was practically complete: no bands of **1** were seen in the spectra after metalation.

IR spectra were measured on a Bruker IFS 113v Fourier transform infrared (FTIR) spectrophotometer in a  $\text{CaF}_2$  cell of 0.13 mm (for 0.20 mol  $\text{l}^{-1}$  DMSO- $d_6$  solutions), a KBr cell of 0.6 mm (for saturated  $\text{CDCl}_3$  solutions), KBr and CsI disks, at a resolution of 1  $\text{cm}^{-1}$  and 50 scans.

## Results and Discussion

### ENERGY ANALYSIS

We calculated the total energies of the most stable conformers of **1** and **2**, as well as that of the tautomeric anion **3** (obtained hypothetically if the metalation had taken place at the phenylamino group) (Fig. 1). Table I shows that the calculated energy difference of the molecular conformers is 4.13  $\text{kJ mol}^{-1}$  and that of the anionic conformers is smaller, 0.87  $\text{kJ mol}^{-1}$ . The energy difference between the most stable anionic and molecular conformers  $E^D = E(\text{anion}) - E(\text{molecule})$  is a measure of the Broensted acidity of a given compound in the gas phase [21]. Georgieva and Velcheva [12] recently found that B3LYP+ $\text{+G}(d,p)$   $E^D$  values of a series of C—H, N—H and O—H acids correlate fairly well (correlation coefficient  $R = 0.94$ ) with the corresponding  $\text{pK}_a$ , measured in DMSO. Having in mind  $E^D = 1444.75 \text{ kJ mol}^{-1}$  (Table I) and the correlation equation  $\text{pK}_a(\text{DMSO}) = 0.11507 \cdot E^D - 150.04$  ( $\text{kJ mol}^{-1}$ ) [12], we estimated a 'theoretical'  $\text{pK}_a(\text{DMSO})$  of sulfanilamide at 16.2. There are no literature data for  $\text{pK}_a(\text{DMSO})$ , but we can suppose that sulfanilamide is a moderately weak N—H acid in DMSO. Deprotonation of sulfanilamide with the formation of **3** is less probable (Table I).

### CORRELATION ANALYSIS

Comparison of the native B3LYP 6-31+ $\text{+G}(d,p)$  vibrational frequencies of sulfanilamide **1a** with those we have measured under various conditions (see the next section, Spectral Analysis) resulted in the formation of excellent correlations ( $0.99 > R > 1$ ; Table II). We shall use them for correlational scalings of theoretical frequencies. According to Alcolea's review article [22], the use of correlation equations instead of scaling coefficients leads to better results, especially for the low-frequency vibrations.

### SPECTRAL ANALYSIS

#### Sulfanilamide- $d_0$

The numerical characteristics of the theoretical and experimental spectra of sulfanilamide **1a** are compared in Table III. Let us consider the solid-state spectrum in the  $\nu_{\text{NH}_2}$  region (Fig. 2, Table III).

With respect to both the method of isolation (experimental) and the IR spectra, our sample corresponds to polymorph I of sulfanilamide [23]. The authors assigned the bands (in the frequency decrease order in the solid-state IR spectrum), as follows:  $\delta_{\text{NH}_2}^{\text{as}}$  (amino),  $\delta_{\text{NH}_2}^{\text{s}}$  (amino),  $\delta_{\text{NH}_2}^{\text{as}}$  (amido), and  $\delta_{\text{NH}_2}^{\text{s}}$  (amido) [23].

However, a new assignment has recently appeared [7] (in the same order):  $\delta_{\text{NH}_2}^{\text{as}}$  (amino),  $\delta_{\text{NH}_2}^{\text{as}}$  (amido),  $\delta_{\text{NH}_2}^{\text{s}}$  (amino), and  $\delta_{\text{NH}_2}^{\text{s}}$  (amido) [7]. We prove the first assignment [23] as follows:

1. Bands at 3462 and 3374  $\text{cm}^{-1}$  (solid state, Table III) are not present in the solid-state IR spectrum of benzenesulfonamide  $\text{C}_6\text{H}_5\text{SO}_2\text{NH}_2$ , and the other two bands appear at almost the same places [24].
2. The solubility of sulfanilamide in chloroform is very low; nevertheless, we succeeded in measuring spectra in  $\text{CDCl}_3$ . All  $\nu_{\text{NH}_2}$  frequencies of the spectra in  $\text{CDCl}_3$  were higher than those in the solid state, due to the strong hydrogen bond destruction. However, amido groups form much stronger hydrogen bonds than are formed by amino groups. This difference resulted in rearrangement of the  $\nu_{\text{NH}_2}$  frequencies, and the new order (solvent  $\text{CDCl}_3$ ) corresponded to the theoretical one (Table III).
3. The substitution of  $^{14}\text{N}$  of the sulfonamide group by  $^{15}\text{N}$  resulted in frequency decreases

**FIGURE 1.** Stable conformers of sulfanilamide (**1a**, **1b**), its anion (**2a**, **2b**) and of the hypothetical anionic tautomer  ${}^{-}\text{NH}-\text{C}_6\text{H}_5-\text{SO}_2-\text{NH}_2$  (**3**).

of the band at  $3343\text{ cm}^{-1}$  by  $11\text{ cm}^{-1}$  and that at  $3247\text{ cm}^{-1}$  by  $7\text{ cm}^{-1}$  (solid state); the bands at  $3462\text{ cm}^{-1}$  and  $3374\text{ cm}^{-1}$  remained at the same places.

Introducing  ${}^{15}\text{N}$  instead of  ${}^{14}\text{N}$  in the sulfonamide group led to the following additional IR changes:

1. Vibration 28 (Table III), dominated by the  $\nu_{\text{S}-\text{N}}$  coordinate, underwent a  $14\text{ cm}^{-1}$  frequency decrease.
2. The computations predicted very close frequencies of vibrations 33 and 34 of the unlabeled sulfanilamide, so we ascribed the band at  $703\text{ cm}^{-1}$  as a superposition of the corresponding bands (Table III). Two new bands,

at 708 cm<sup>-1</sup> and 697 cm<sup>-1</sup>, with opposite isotopic shifts (+5 and -6 cm<sup>-1</sup>) appeared in the spectrum of sulfanilamide-<sup>15</sup>N instead of the cited above band superposition.

- These results can be considered as proof for the assignments of the bands mentioned. We shall also discuss the IR spectrum of sulfanilamide-d<sub>0</sub> with the relation to both deuteration and conversion into azanion in the next subsections.

#### Sulfanilamide-d<sub>4</sub>

The solid-state IR spectrum of this compound is compared with the spectrum of the nonlabeled species in Figure 2. We can see the high deuteration level of our sample. The numerical theoretical and experimental IR characteristics of sulfanilamide-d<sub>4</sub> (labeled in the amino groups) are listed in Table IV.

It is also seen in Table IV and Figure 3 that the deuteration has led to very essential IR changes affecting mainly vibrations with decisive participations of the two NH<sub>2</sub> groups. The large negative

isotope shifts correspond to  $\nu_{\text{NH}_2}^{\text{as}}$ ,  $\nu_{\text{NH}_2}^{\text{s}}$  and  $\delta_{\text{NH}_2}^{\text{sc}}$  vibrations of both amino and amido groups. As should be expected on the basis of the computations (Table IV), the isotope shifts of the remaining IR bands are not essential.

The  $\Delta\Delta\nu$  value (the last column of Table IV) is a quantitative measure of the agreement between theoretical and experimental isotope shifts. Their sum is 288 cm<sup>-1</sup>, the sum of the absolute values of the experimental isotope shifts  $\Sigma/\Delta\nu_{\text{exp}}$  is 4197 cm<sup>-1</sup>, and the ratio of the sums is 0.069 or 6.9%. The latter result should be considered a very good one, as the frequency shifts are more sensitive, hence more informative than the frequencies themselves for estimating the accuracy of the computations [25]. For example, the corresponding ratio value in the case of nicotinamide-d<sub>0</sub> and -d<sub>2</sub> was found to be essentially large (i.e., worse), 18.3% [25].

#### Sulfanilamide Azanion-d<sub>0</sub>

Organic anions are not soluble in common spectroscopic solvents and usually react with them. So,

polar aprotic solvents, most frequently DMSO, are used to study the IR spectra of organic anionic derivatives (Refs. [8–12, 14, 19, 20, 26] and references therein). Sulfanilamide azanion (e.g., sulfanilamide itself) is highly soluble and very stable in DMSO. To perform a correct comparison of the IR spectra of sulfanilamide- $d_0$  and - $d_4$  with those of their azanions, we shall consider their DMSO solution spectra (Tables V–VIII and Fig. 3). As in the preceding subsection, we shall now use theoretical data for the most stable conformers **1a** and **2a** of the species studied (Table I, Fig. 1).

The frequencies of the very strong  $\nu_{\text{SO}_2}^{\text{as}}$  and  $\nu_{\text{SO}_2}^{\text{s}}$  bands measured in DMSO (Table V) agree well with those measured in the solid state (cf. Table III). The theoretical method used predicts these frequencies fairly well: the sum of their B3LYP 6-31++G(*d,p*) values is only 32  $\text{cm}^{-1}$  (native) or 37  $\text{cm}^{-1}$  (scaled) less than the sum of the frequencies measured experimentally. For comparison, the corresponding deviation, found by the authors [7] at the ab initio HF 3-21G level, was  $-519 \text{ cm}^{-1}$  (native). The same investigators obtained a much larger deviation,  $-865 \text{ cm}^{-1}$  (native) on the basis of PM3 calculations [27].

By analogy with the cases of sulfanilamide- $d_0$  and - $d_4$  in the solid state, we compared the IR spectra of same species in DMSO- $d_6$  solutions (Table VI). We calculated a value  $\sum \Delta \nu_i / \sum \nu_{i(\text{exp})}$  of

17.4% in the present case or 2.5-fold larger (i.e., worse) than that found in the preceding subsection.

Now we can compare data in Tables V and VII and in VI and VIII; these comparisons will make it possible to discuss the IR changes, caused by the conversion of sulfanilamide- $d_0$  and - $d_4$  into the corresponding azanions - $d_0$  and - $d_3$ .

We can see in Tables V and VII and Figure 3 that the conversion produces essential IR spectral changes:

1. Both  $\nu_{\text{SO}_2}^{\text{as}}$  and  $\nu_{\text{SO}_2}^{\text{s}}$  bands undergo essential frequency decreases, which sum is: predicted 122  $\text{cm}^{-1}$ , measured 140  $\text{cm}^{-1}$ . The latter value is rationally lower than the corresponding decreases found in other cases of molecule  $\rightarrow$  azanion pairs, containing additional electron-withdrawing groups (compound,  $\Delta \nu_{\text{SO}_2}$  sum): *o*-sulfo benzimidazole (saccharin), 93  $\text{cm}^{-1}$  [28]; *o*-sulfo thiobenzimidazole (thiosaccharin), 60  $\text{cm}^{-1}$  [29].
2. The **1a**  $\rightarrow$  **2a** conversion studied leads to a 1.6-fold increase in the sum of the integrated intensities of the phenylene bands  $\delta_{a,b}$  and  $19_{a,b}$  (Wilson's notation). This result is in agreement with the intensity increases of those bands in cases of many other anionic substituents [30].

TABLE IV

Theoretical [B3LYP 6-31++G(d,p)] and experimental (solid, in KBr) IR frequencies ( $\nu$ , in  $\text{cm}^{-1}$ ) and integrated (A in  $\text{km mol}^{-1}$ ) or relative intensities of sulfanilamide-d<sub>4</sub>, and the corresponding isotope shifts.

in the present case correspond to the  $\nu_{\text{SO}_2}^{\text{as}}$  and  $\nu_{\text{SO}_2}^{\text{s}}$  vibrations. The calculations predict essential decreases of their frequencies caused by the deuteration but, according to the experimental data, these effects are close to zero (Table VIII).

## STRUCTURAL ANALYSIS

We shall try to elucidate the steric and electronic structures of sulfanilamide **1a** and its azanion **2a**. The results will make it possible to follow the structural changes caused by the **1a** → **2a** conversion.

### Steric Structures

The steric structures of the most stable conformers of sulfanilamide and its azanion are shown in Figure 1; the numerical theoretical and experimental (X-ray diffraction for **1a** only [31–33]) values of the corresponding parameters are compared in Table IX.

We can see in Table IX very good agreement between theoretical and experimental bond lengths

of sulfanilamide molecule: the mean absolute deviation (m.a.d.) between them is 0.019 Å. The largest individual deviation of 0.077 Å corresponds to the S<sup>8</sup>—N<sup>11</sup> bond and can be related to the formation of hydrogen bonds in the crystal state. The m.a.d. value with respect to the bond angles is 1.41° (Table IX). The results obtained can be considered very good, with m.a.d. values comparable to the average experimental errors (0.01–0.02 Å and 1°–2° [31–33]). In contrast, no one could expect full coincidence between experimental data for the crystal state and theoretical values, computed for an isolated sulfanilamide molecule.

There are no experimental structural data for sulfanilamide azanion. The calculations predict (Table IX, last column) that the largest structural variations, caused by the **1a** → **2a** conversion, should take place both at (shortening of the S<sup>8</sup>—N<sup>11</sup> bond by 0.120 Å) and next to it (lengthening of the C<sup>4</sup>—S<sup>8</sup> bond by 0.056 Å). This rule is also valid for the bond angles (Table IX); it agrees with the data for carbanions, oxyanions, and other azanions (Refs. [10, 13, 14, 19, 34] and references therein).

<sup>a</sup> For the atom numbering, see Scheme 2.

<sup>b</sup> Mean values for three polymorphic forms [31–33].

<sup>c</sup> Algebraic deviations (Å, degrees) between theoretical and experimental values.

<sup>d</sup> Algebraic deviations (Å, degrees) between theoretical values of the anion and molecule.

<sup>e</sup> Mean absolute deviation between theoretical and experimental values.

## Electronic Structures

The net Mulliken electric charges  $q_i$  over fragments of the molecule **1a** and azanion **2a** of sulfanilamide are shown in Scheme 2. The charge change values  $\Delta q_i = q_i$  (anion)  $- q_i$  (molecule) are usually quite informative in showing the distribution of the new (e.g., carbanionic, azanionic) changes in anions (Refs. [10, 11, 13, 14, 19, 20, 28, 29, 34] and references therein). According to the present calculations, the new (azanionic) charge of **2a** is distributed, as follows:  $0.08e^-$ ,  $0.23e^-$ , and  $0.12e^-$  are delocalized over the amino, phenylene, and sulfonyl groups, respectively, and

$0.57e^-$  remain localized at the azanionic center (cf. Scheme 2).

We believe that the calculated net charges of **1a** are not from the real ones, based on the following

**SCHEME 2.** Net Mulliken electric charges  $q_i$  of fragments of the molecule **1a** and azanion **2a** of sulfanilamide.

criteria: (i) we calculated a dipole moment of sulfanilamide  $\mu$  of 5.18 Debye; (ii) the following  $\mu$  values (in Debye) of this molecule were found: 7.1 (pyridine, 25°C), 6.60 (dioxane, 25°C), 6.22 (benzene/dioxane, 25°C) [35–37]; and (iii) all the experimental values are larger than the theoretical one, but the order of their increase corresponds to the increase in the ability of the solvents to form strong hydrogen bonds with the sulfanilamide molecule.

## Conclusion

The comparisons, performed in this work between experimental (in cases where they are available) and B3LYP 6-31++G(*d,p*) data, showed good agreement for the IR spectral changes, caused by the molecule  $\rightarrow$  azanion conversion, and a very good agreement for the structural data of the sulfanilamide molecule. We anticipate that the structural data, predicted by the same theoretical method for sulfanilamide azanion and (therefore) the structural changes, accompanying the above conversions should also be adequate.

## Acknowledgment

The authors thank Professor I. G. Binev, Ph.D., D. Sci., for useful discussion.
